MEASURING DIELECTRIC CONSTANTS AS A METHOD FOR GAS ANALYSES. K. D. Perumova, L. V. Gavrilova, Oleg Zaitsev, N. A. Kuchkina, Litera B-11, Novosibirsk, 1935, pp. 213. The dielectric const. of butyryl vapors (0.0028) and that of isobutylene (1.022 at 100 mm. and 10°). Curves are constructed for various proportions of the above ingredients. The accuracy of dielectric constants of the above gases by means of elec. waves is of the magnitude of 0.001%. For butyryl and isobutylene the dielectric const. are of an additive nature. The mol polarization of nonpolar hydrocarbons of the type C_nH_{2n} , $\text{C}_n\text{H}_{2n+2}$, and $\text{C}_n\text{H}_{2n+4}$ is directly proportional to their mol. wt. It is possible to classify with respect to the polarity and μ (dipole moment) of polar hydrocarbons of the above type by means of the obtained relationship of the mol polarization to the mol. wt. for nonpolar hydrocarbons and the value of the mol polarization of the given hydrocarbon. The exptl. procedure is described. Twenty three references.

TITLE: Work-Hardening of Bismuth Under Conditions of Programmed Loading 27

PERIODICAL: Fizika metallov i metallovedeniye, 1961, Vol.11, No.1,
pp.108-114

TEXT: Increasing the rate of deformation, or lowering the temperature, brings about an increase in the work-hardening exponent; this effect is attributed to the fact that under these conditions duration of the relaxation process during deformation decreases. At relatively higher temperatures, the work-hardening exponent decreases owing to increased intensity of relaxation. However, it has been shown by Bol'shanina (Ref.1) that the yield point of twinned calcite increases five times after annealing, while Garber et al (Ref.3) have found that the yield point of iron, twinned at the temperature of liquid helium, also rapidly increases during subsequent heating to room temperature. The object of the present investigation was to elucidate the mechanism of these effects by studying work-hardening of bismuth. Since twinning is

Card 1/10

E193/E483**Work-Hardening of Bismuth Under Conditions of Programmed Loading**

the predominant mechanism of plastic deformation of this metal, it was assumed that its mechanical properties would be similar to those of twins in calcite and iron. Refined bismuth was used for the preparation of the experimental test pieces, made by the Bridgeman method, in the form of rods (180 mm long, 5 mm in diameter) with spherical ends, and subsequently vacuum-annealed at 200°C for 3 h. The experiments consisted in straining the test pieces in tension at room temperature under controlled conditions. The tensile force was applied by means of weight, hung at the lower end of the specimen, the usual precautions having been taken to ensure axial loading. The load was increased in a pre-determined fashion by means of an automatic dispenser from which small balls dropped at regular intervals into a container which constituted the loading weight. Each load increment did not exceed 6×10^{-3} g/mm², and the average rate of loading was maintained constant throughout each experiment, the rates applied varying between 2 and 10 g/mm²/h. It was found in the course of experiments that it was possible to select a certain critical rate of loading

Card 2/10

σ_k at which the rate of deformation $\dot{\epsilon}$ remained constant within a wide interval of applied stress. This can be seen in Fig.2, where elongation ϵ ($10^3\%$, left-hand scale) and stress σ (g/mm^2 , right-hand scale) are plotted against time t (hours). To make sure that the test piece had, in fact, undergone plastic deformation, ϵ was measured while the load was gradually removed. The results (broken curves in Fig.2) show that although some elastic recovery had taken place, more than a half of the elongation, attained at the end of the loading cycle, was due to plastic deformation. Fig.3 shows two $\sigma(\epsilon)$ curves, constructed for two identical specimens, loaded at $\sigma < \sigma_k$, the upper and lower graphs relating to specimens loaded at 2.3 and $4.5 \text{ g/mm}^2/\text{h}$, respectively. It will be seen that in both cases, the work-hardening exponents $\partial\sigma/\partial\epsilon$ remained constant. The results of the next series of experiments are reproduced in Fig.4, where elongation ϵ (<%, left-hand scale) and stress σ (g/mm^2 , right-hand scale) are plotted against time t (hours). Graph 1, $\sigma(t)$ and 2, $\epsilon(t)$ relate to a specimen tested in the following way:

Card 3/ 10

S/126/61/011/001/010/019
E193/E483

Work-Hardening of Bismuth Under Conditions of Programmed Loading

the load was applied at a rate $\dot{\sigma} = 8 \text{ g/mm}^2/\text{h}$ until a certain σ_m was reached at which the $\epsilon(t)$ relationship ceased to be linear; beginning from this moment, the load was maintained constant at σ_m for 24 h during which time the test piece continued to deform owing to creep; the rate of creep during this period remained constant and was practically the same as the rate of strain during the preceding period. For comparison, Fig.4 shows a creep curve (graph 3) of another specimen which has been loaded to σ_m in 20 min. It will be seen that in this case the total deformation was higher than that of the test piece strained under slow rate of loading, and that the rate of creep under this constant stress σ_m was also considerably higher. The interesting fact is that in the case of specimens, work-hardened during deformation at slow rate of loading and then re-loaded at a fast rate to σ_m , the rate of creep decreased 2 to 3 times (see right-hand branch of graph 2, Fig.4). It was also found that test pieces, work-hardened by deformation at slow loading rates, did not lose their strength after ageing (with the load taken off) at room temperature. The results described above confirm the hypothesis put forward by Garber (Ref.4),
Card 4/10

E193/E483

Work-Hardening of Bismuth Under Conditions of Programmed Loading

according to whom the observed effects are due to diffusion strengthening of twins which is brought about by aggregation of vacancies and impurity atoms at the twin boundaries. In cases when twins do not traverse the cross-section of the test piece, diffusion strengthening may inhibit further growth of the twins even at relatively high loads. It was for this reason that no traces of twins were observed on the surface of the test pieces used in the experiments described above and that deformation took place under conditions of equilibrium, as indicated by the absence of discontinuities on the $\epsilon(t)$ curves. Different results were obtained when a test piece in the form of a single crystal, 1.2 mm in diameter, was used. This is illustrated by graphs in Fig.5, where $\Delta\ell$ (microns, left-hand scale) and σ (g, right-hand scale) are plotted against time t (hours). Sudden jumps on the $\Delta\ell(t)$ curve for a test piece under load which increased at a constant rate indicate that work-hardening, caused by diffusion-induced enrichment of the twin boundaries in vacancies and impurity atoms, cannot prevent the formation and growth of twins in a specimen of Card 5/10

89943

E193/E483

Work-Hardening of Bismuth Under Conditions of Programmed Loading

this size. In the case of high quality single crystals of small cross-section area, a twin nucleus (e.g. an elastic twin) can rapidly change into a twin intersecting the cross-section of the specimen, as a result of which deformation of the specimen proceeds in jumps, since the resistance to deformation (by twinning) at the moment of the formation of a twin decreases several times. The $\Delta\ell(t)$ and $\sigma(t)$ curves for such a specimen (a single crystal with the gauge length of 150 mm and rectangular cross-section 3 x 2.5 mm) are shown in Fig.6. In spite of very slow rate of loading employed, it was found impossible to obtain gradual deformation (i.e. smooth $\Delta\ell(t)$ curves) of the specimens, on the surface of which evidence of twins, intersecting the cross-section, was found after completion of the loading cycle. That these effects were observed in a rectangular specimen can be attributed to non-uniform distribution of stresses over its cross-section and to the high quality and homogeneity of its crystal structure. Finally, in order to elucidate the nature of the processes leading to work-hardening of specimens deformed at slow and fast rates of Card 6/10

89943

S/126/61/011/001/010/019
E193/E483**Work-Hardening of Bismuth Under Conditions of Programmed Loading**

loading, X-ray diffraction patterns of test pieces, loaded to the same σ_m (yield point) but at different rates of loading (8 and 1080 g/mm²/h), were obtained. The pattern obtained for the slowly loaded specimen hardly differed from that obtained for an undeformed material, whereas a very different pattern was obtained on the specimen deformed at a fast rate of loading. This indicated that work-hardening under normal conditions of loading (within the elastic region) is associated with fragmentation of the crystal, whereas all other factors being equal, deformation under conditions of slow rates of loading does not affect the crystal structure or affects it only in the regions of lowest strength which constitute a minute fraction of the total volume of the crystal. Acknowledgments are made to I.M.Fishman and S.T.Shavlo, who participated in this work. There are 9 figures and 11 Soviet references.

ABSTRACT: This Author Certificate introduces a method of measuring
the displacement of points of a structure in static tests in thermoaeo-
dynamic tubes. To ensure high precision and reliability of measure-
ments at high temperatures each point is provided with a marker
carrying two cylindrical rods mounted at a given distance from each
other. The markers are illuminated and photographed prior to and
during testing at given periods of time. On a developed negative, the
scale for each point is determined and used for measuring the magnitude
of the shift of the points. Orig. art. has: 1 figure. [MS]

ABSTRACT: This Author Certificate presents an attachment to a hay stacker-loader for
loading of airplanes and other transports with mineral fertilizers and granular
chemicals. The attachment includes a working member in the shape of a scoop with
connecting elements to the lifting boom of the loader (see Fig. 1). For loading of
mineral fertilizers and grain chemicals, the tractor boom is equipped with a hinged
extension frame for attachment of the scoop which is equipped with a door on the
discharge side of the scoop. The door can be activated by the operator. A second
version has the scoop pivot located at the top portion of the scoop to provide great-
er opening of the discharge opening. A third feature provides stops on the

AUTHOR: Lipatov, Yu. S., Perushkina, N. G., Vasilenko, Ya. P., and Sergeyeva, L. M.

TITLE: The adhesion of polymers to a solid surface and their adsorption from solutions

PERIODICAL: Akademiia nauk Belaruskay. Doklady, v. 6, no. 1, 1962, 42-44

TEXT: Gelatine water solutions and copolymers of styrene with methacrylic acid in organic solvents on the surface of glassfiber—were investigated by a method similar to that described in a previous paper (Ref. 6). Yu. S. Lipatov, L. M. Sergeyeva, V. P. Maksimova, Vyskomoleksoyed., 2, 1570, 1960). The concentration was determined by means of a spectrometer CΦ-4 (SF-4) with precision up to 0.001%. The copolymer solutions was determined by means of a nephelometer ΦM-56 (FM-56) with exactness up to 0.01%. Adsorption of copolymers with distribution of 1.6% and 24% of methacrylic acid was investigated. In cases of gelatine in water solution the adsorption is low, but it attains a maximum, (see Ref. 2, Yu. S. Lipatov, DAN BSSR, v. 5, 69, 1961). Adsorption of a copolymer with a distribution of 1.6% of methacrylic acid there is no adsorption from solvents of the copolymer. Comparison of the adsorption and adhesion shows that there is no direct link between adhesion of the polymer and its adsorption in spite of their dependence on the interaction between functional groups in the polymers molecule's form and the surface groups. There are different conditions for adsorption from

1048. INVESTIGATION ON THE BIOLOGICAL PROPERTIES OF HAEMOLYTIC STREPTOCOCCI IN SCARLET FEVER, SUPERINFECTION AND COMPLICATIONS (Russian text) - Pervachenko S. V. - PEDIATRIIA 1957, 1 (15-22) Graphs 5

The complications in scarlet fever appear only when the new serological types of haemolytic streptococci (as a result of cross-infection) are more toxigenic than the initial strains. These differences in toxigenicity are very expressive. In the course of uncomplicated cases of scarlet fever the new serological types of haemolytic streptococci have always the same or even lower toxigenicity than the initial strains. The author did not notice any dependence between the virulence of the investigated streptococcal strains and the appearance of scarlatinal complications.

Purified scarlet fever toxin was obtained by fractional alcohol precipitation. The titre of purified toxin was 500,000 skin doses per 1 ml. Protein content was only 1/18 of that in the native toxin. The purified toxin was rendered atoxic by fractional addition of 0.5% formaldehyde at 40° C. for 30 days. Toxicity decreased to 2,000 skin doses per 1 ml. This anatoxin had considerably lower antigenic properties than the toxin.

AUTHOR: Pervachev, S. V.

TITLE: Collapse of tracking in an automatic time selector 25

SOURCE: Radiotekhnika i elektronika, v. 10, no. 8, 1965, 1435-1444

TOPIC TAGS: time selection

ABSTRACT: The collapse of tracking of an automatic time selector (a nonlinear servo) describable by a second-order differential equation is analyzed by means of the Focker-Planck equations. Formulas are developed for calculating the probability P of collapse of tracking (servoing) in a selector that has integrating and proportional-integrating filters; the formulas are valid for $P < 0.2$. The formulas were verified on an analog computer. They permit calculating the required signal-to-noise ratio at a discriminator output on the basis of a given tolerable probability of collapse. The formulas are applicable to other servosystems, e. g., angle or frequency types, which are describable by the same equations as the time selector. Orig. art. has: 3 figures and 47 formulas.

TITLE:

On the capture bandwidth of a phase-type automatic frequency control system

PERIODICAL:

Radiotekhnika i elektronika, v. 8, no. 2, 1963,
334-337

TEXT: Several authors, among them Richmen and Gruch, have considered the value of the capture bandwidth of a phase-type AFC system with a proportional-integrating filter (transfer function $(1 + pT_1)/(1 + pT)$) between the phase detector and the reactance tube, but their results are incomplete and contradictory, the divergence being very large in some instances. The author has approached the problem by using an analog computer to solve the basic differential equation of the system and so find the conditions for the existence of a limiting cycle. He gives families of curves of capture bandwidth against $\Delta = (8/\pi)\Omega T$ (Ω being the synchronization bandwidth of the system) for various values of $n = T_1/T$, with both poly-

Card 1/2

gonal and sinusoidal phase detector characteristics. These curves have been checked experimentally and found to agree within 10%. They can be used for assessing the properties of given AFC systems, and also for design calculations on such systems. There are 3 figures. The English-language reference reads as follows: D. Richmen, Proc. I.R.E., 42, 1, 1954, 106; W. Gruen, Proc. I.R.E., 41, 8, 1953, 1043.

TITLE: Investigating the synchronization state of a follow-up auto-selector

PERIODICAL: Radiotekhnika, v. 17, no. 2, 1962, 51 - 55

TEXT: The author considers the lock-in state of a follow-up auto-selector, in which the initially separate frequencies of repetition of signal and synchronization pulses become equal owing to the turning effect of the reactance valve. This synchronism is set-up when the initial repetition frequency difference and the inertia of the follow-up system, as determined by the filter, are small. Otherwise the locking-in does not occur. The lock-in range is understood to be the maximum frequency difference of signal repetition and of stroboscopic pulses, at which synchronism occurs. The dependence of the lock-in range is analyzed as a function of the auto-selector being described by the differential equation analogous to that of

Card 1/43

Investigating the synchronization ... S/108/62/017/002/007/010
 D201/D305

phase-self locking system (PSLS) of continuous oscillations. This approach makes it possible to apply the method of analysis developed by M.V. Kapranov for determining the locking range of PSLS (Ref. 2: Radiotekhnika, v. 11, no. 12, 1956; Izvestiya vuzov MVSSO SSSR, Seriya Radiotekhnika, no. 4, 1958). In the present article, the locking band of the autoselector is determined, assuming that the filter Φ has inertia and transfer coefficient equal to $1/(1+pT)$. Since a follow-up autoselector is a pulse control system, to determine the locking range the phase plane analysis and conditions of the existence of the limit cycle passing through the saddle point of equilibrium, are used. By introducing the dimensionless filter time constant $\Delta = \frac{2}{\pi\lambda^2} = \frac{8}{\pi} \cdot \Omega T$, where Ω - the synchronization range in angular frequencies, T - the filter time constant and $q = l/\tau_s$, where l - the repetition frequency of synchronization pulses and τ_s - the synchronizing pulse duration, the synchronization range γ_s becomes a function of the equivalent time constant of the

Title : Quantitative determination of alkyl-substituted 1-methyl-4-piperidones

Periodical : Zhir. anal. khim. 9/5, 304-307, Sep-Oct 1954

Abstract : Methods for quantitative determination of pure alkyl-substituted 1-methyl-4-piperidones and 1-methyl-4-methylinopiperidones in technical products are described. Results obtained by titration with hydrochloric acid and bromo-cresol green as an indicator and formation of oximes after neutralization with hydrochloric acid, are described in detail. Two USSR references (1948 and 1952). Table.

vysoty i chasti snega na l'du na khodu sudna. /A new method
of determining the thickness of ice, and of snow on the ice,
from a moving ship./ Meteorologija i Gidrologija, No. 7:44-46,
1952. 2 figs., 2 refs. DIC—The authors criticize previous methods
of ice and snow thickness measurement and describe a new instrument.
A small tube is attached parallel to the end of a rod
60 cm long. A frame is located near the other end of the rod
(14 x 22 cm) with a Flexiglass plate on which a rectangular grid
is drawn (size of each square 20 x 20 mm). The grid can be
moved along the rod. The rod is placed vertically outside the
ship and the observer marks how many squares of the grid are
covered by ice. Thickness of ice and snow is determined by a
method of similar triangles. Subject Headings: 1. Ice
thickness measurement. 2. Snow Surveys.

KHOTKEVICH, V.I. [Khotkevych, V.H.]; PERVAKOV, V.A. [Pervakov, V.O.]

Investigating the temperature dependence of the electric
resistance of plastically deformed copper during cooling. Ukr.
fiz. zhur. 4 no.6:755-759 N-D '59. (MIRA 14:10)

1. Khar'kovskiy ordena Trudovogo Krasnogo Znameni gosudarstvennyy
universitet im. A.M.Gor'kogo i Fiziko-tehnicheskiy institut
AN USSR.
(Metals at low temperature) (Deformations (Mechanics))
(Copper---Electric properties)

PERVAKOV, V. A. and KHOTKEVICH, V. I.

"Calorimetric Determination of the Energy of Formation of Vacancies in Gold."

report read at the Intl. Conference on Semiconductor Physics, Prague,
29 Aug - 2 Sept 1960.

Physics Technical Inst, Ukr Acad. Sci.
Khar'kov State University im. A. M. Gor'kij

KHOTKEVICH, V.I.; PERVAKOV, V.A.; MERISOV, B.A.

Temperature relation of the electric resistance in plastically deformed silver and copper. Fiz. met. i metalloved. 9 no. 4:637-639 Ap '60. (MIRA 14:5)

1. Khar'kovskiy gosudarstvennyy universitet im. A.M. Gor'kogo
i Fiziko-tehnicheskiy institut AN SSSR.
